

Data Science Project Report

Analysis of Bangladesh Cricket Board (BCB) News Dataset (CSV)

1. Objective

The goal of this project is to analyze a news dataset (in CSV format) collected from tigercricket.com.bd, in order to understand the dataset's structure, category-wise trends, and content characteristics. This is a basic Exploratory Data Analysis (EDA) task, where statistical summaries and visualizations are used to understand the data.

2. Dataset Description

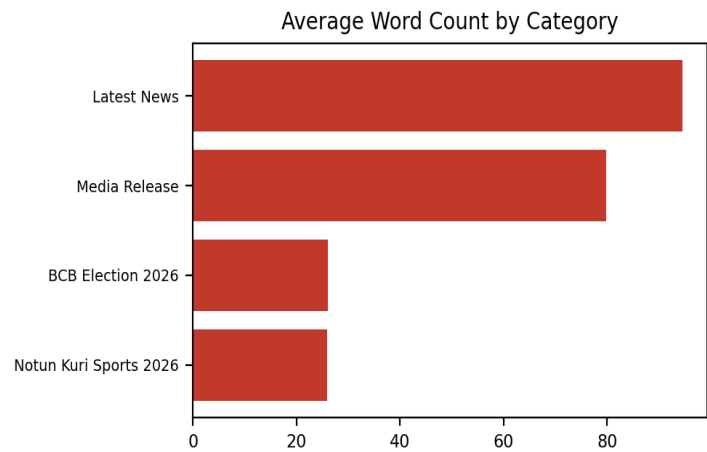

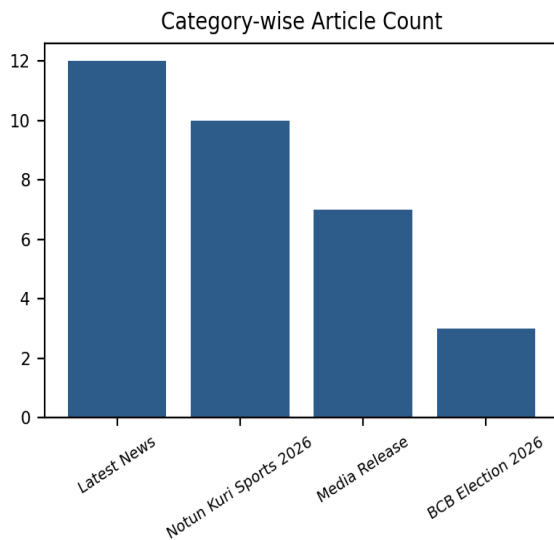

The dataset contains 32 news articles with 8 columns: title, category, published_date, author, url, image_url, content, and word_count. The publication period spans from 23 August 2025 to 25 July 2026. All articles are authored by 'Staff Correspondent'. The dataset covers four categories: Latest News, Notun Kuri Sports 2026, Media Release, and BCB Election 2026.

3. Methodology

The CSV file was loaded using Python's pandas library. The data was then grouped by the category column to compute article count and average word_count per category. matplotlib was used to visualize the results through bar charts.

4. Analysis & Findings

Category	Article Count	Avg. Word Count
Latest News	12	94.6
Notun Kuri Sports 2026	10	25.9
Media Release	7	79.9
BCB Election 2026	3	26.0

Key Observations:

- 'Latest News' has the most articles (12) and the highest average word_count (~95 words), since it includes longer feature articles and detailed media notices.
- 'Notun Kuri Sports 2026' has 10 articles, mostly short match-result updates (average word_count ~26), so its content is brief.
- 'BCB Election 2026' has the fewest articles (3), but related election news is also spread across 'Latest News' and 'Media Release', showing that election coverage is a major theme across the entire dataset.
- The overall average word_count is 63.5 words, but the median is only 20.5 — meaning most articles are short notices, while a few long feature articles (e.g., the women's cricket history piece, 476 words) pull the average up.

5. Conclusion

This analysis shows that the BCB news dataset is mainly divided into two content types — short official notices/updates (elections, match results) and longer feature/media release articles. Analyzing the variation in word_count by category makes it easy to identify patterns in the data, which could be useful for future text classification or content recommendation systems.
